Environmental variation can shape phenotypic variation in organisms, but most evidence for trait differentiation comes from analyses of dichotomous habitat types that differ in only one or few key environmental factors. In reality, environmental variation is often more subtle, gradual and multifarious. Here, we investigated geographic variation in body shape of two darter species (Etheostoma spectabile and Etheostoma flabellare; Percidae) that occur along river gradients.

The distribution of three species of darters (Percidae) was studied with respect to vegetation and substrate preferences. The distribution of these darters was correlated with presence of vegetation. Quantitative field data were combined with a laboratory evaluation of preference to determine the sensory mechanisms operating in habitat selection.

As suggested by the emerald darter's subterminal mouth, they are benthic feeders, primarily consuming small invertebrates such as microcrustaceans, various types of larvae, and nematodes. Emerald darters tend to feed during the day, and their diets largely depend on the time of year, as prey availability changes due to season.
